“On the way with Python”

Lecture

03

Python Input/Output

Md. Shakil
Assessor & Trainer
National Skill Development Authority

Introduction

Input and Output (I/O) are essential parts of any programming language. Input is used to take data from the user, and Output is used to display results to the user. Python provides simple and powerful functions for handling input and output.

“Output in Python”

Output in Python

Python uses the **print()** function to display output on the screen.

```
print("Hello, World!")
```

Printing Variables

```python
name = "Python"
age = 30
print(name)
print(age)
```

Printing Single Value

```python
print("Name:", name, "Age:", age)
```

Printing Multiple Values

Formatting Output

Using Comma (,): Automatically adds space between values.

```
print("Hello", "Python")  # Output: Hello Python
```

Using f-strings:

```
name = "John"
age = 25
print(f"My name is {name} and I am {age} years old")
```

Formatting Output

Using format() Method

```
print("My name is {} and I am {} years old".format(name, age))
```

Using % Operator

```
print("My name is %s and I am %d years old" % (name, age))
```

“Input in Python”

Input in Python

Python uses the **input()** function to take input from the user.

```python
name = input("Enter your name: ")
print(name)
```

Important Note: The input() function always returns data as a string.

Type Conversion with Input

To perform calculations, input values must be converted into required data types.

```python
age = int(input("Enter your age: "))
print(age)
```

Integer Input

```python
price = float(input("Enter price: "))
print(price)
```

Float Input

Taking Multiple Inputs

```python
a = int(input("Enter first number: "))
b = int(input("Enter second number: "))
print(a + b)
```

Using Multiple input() function calls

```python
a, b = input("Enter two numbers: ").split()
print(int(a) + int(b))
```

Using split()

""Thanks All""
